Summary

Project

- Analysis of kauri dieback soil samples, Phase 1, March–August 2011.

Objectives

- Using the extended soil baiting SOP, bioassay soil samples collected as part of the delimitation survey for presence of *Phytophthora* taxon Agathis (PTA)
- Provide interpretation of results in relation to PTA status of the soil samples.

Methods

- Soil samples received from Wildland Consultants were logged at Landcare Research, Tamaki, provided a discrete sample number, weighed and stored at 10°C before bioassay.
- Soil samples were thoroughly mixed in the bag and sub-sampled for analysis by at least one of three diagnostic laboratories: Landcare Research (Tamaki); Scion (Rotorua) and Plant and Food Research (Havelock North). Soil samples were packaged and sent via overnight courier to Scion and Plant and Food Research (PFR).
- A standardised, extended soil baiting bioassay protocol using germinated lupin seed (*Lupinus angustifolius*) and Himalayan cedar needles (*Cedrus deodara*) was employed at all three laboratories. The bait tissues were plated to *Phytophthora*-selective media and characteristic PTA-cultures recovered.
- Eighteen soil samples that recorded negative for PTA were reanalysed using the extended baiting protocol.

Results

- Phase 1 comprised 91 samples representing 25 sites.
- Soil samples ranged in mass from 1 to 6 kg, most being between 1 and 4 kg.
- PTA was recovered from 15 of the 91 samples, representing seven of the 25 sites and coming from five forest areas. The five forest areas with PTA-positive sites were Waipoua, Omahuta, Glenbervie, Punaruku (Russell Forest) and Great Barrier Island.
- There was marked clustering of PTA-positive recoveries from within an infested site.
- *Phytophthora cinnamomi* was recovered from 60% of the samples.
- *P. multivora* was recovered from 5.5% of the samples.
- 30% of samples had no *Phytophthora* recoveries.
- We obtained the same results for the repeated soil bioassays for selected previously PTA-negative sites – these remained negative for PTA.

Conclusions

- Using the extended soil baiting method, PTA was recovered from the following soil samples submitted by Wildlands Consultants:
 - Waipoua Site 5

- Omahuta Site 6
- Glenbervie Sites 19A, 19C, 19D
- Punaruku (Russell Forest) Site 28
- Great Barrier Island Site 21.
- There was marked clustering of PTA-positive recoveries from within an infested site.
- There was considerable variation between the sizes of soil samples and standardisation would be desirable.
- Preventing the overheating of soil samples is vital as PTA mycelium is killed at 29°C and viability of oospores will likely be reduced at temperatures above 45°C.

Recommendations

- Standardise soil volume at point of sampling (1–1.5 kg).
- Modify the QA/QC procedure to include temperature monitoring of soil from the point of sampling through to the analytical laboratory. In this way, temperature data can be analysed upon receipt of each sample, to establish if significant temperature variations (i.e. >30°C) have occurred in transit.
- Establish a ‘cool chain’ of custody to maintain soil sample temperatures below 25°C and preferably within the range 10°C ± 50%.
- Temperature tags (e.g. iButtons®) should accompany soil from the point of sampling, through to laboratories.
- Delimit extent of contaminated sites through further sampling (including, where appropriate, tissue sampling).

1 Introduction

Phytophthora taxon Agathis (PTA) is an oomycete fungus associated with dieback in kauri *Agathis australis* trees in Auckland, Northland and Great Barrier Island and possibly other sites where dieback occurs but PTA has not yet been identified.

The Ministry of Agriculture and Forestry (MAF) is working in partnership with the Department of Conservation, regional councils and local iwi to deliver a long-term management programme for kauri dieback. As part of this programme, and on behalf of the programme partnership, MAF requires analysis of soil and tissue samples taken from approximately 20 forests throughout the natural range of kauri. This final report provides a summary of results from Phase 1 of the Soil Detection Plan (SDP), and incorporates feedback from the Planning and Intelligence Committee of the Kauri Dieback Joint Agency Response.

2 Background

PTA has been identified as a causal agent of kauri dieback (Beever et al. 2009) and new sites of kauri dieback continue to be identified across the Auckland and Northland regions. The current distribution of PTA includes sites in Northland (Ratea Plantation, Waipoua, Trounson, Mangawhai) and Auckland (Waitakere Ranges, Great Barrier Island, Awhitu and the Hunua Ranges). Not all kauri forests throughout the North Island have been surveyed for PTA, and these could represent disease-free remnants that need to be identified and protected appropriately.

Through a process of consultation, the Kauri Dieback Joint Agency Response (KDJAR) has gained access to survey the kauri estate of the North Island. This first stage of the soil sampling process is being carried out by Wildland Consultants, and covers sites from Northland, Coromandel and Great Barrier Island.

3 Objectives

- Using the extended soil baiting SOP, bioassay soil samples collected as part of the delimitation survey for presence of *Phytophthora* taxon Agathis (PTA).
- Provide interpretation of results in relation to PTA status of soils.

4 Methods

4.1 Soil receipt protocol

Soils were sampled by representatives of Wildland Consultants according to a protocol provided by the KDJAR (Dick & Bellgard 2010) and delivered to Landcare Research, Tamaki, where they were inspected to ensure they were intact. The waterproof labels were removed from the individually bagged samples, which were given unique sample identity numbers. These were recorded on a hard copy of the Sample Receipt and Record Log (Appendix 1A) and their weight recorded on the Sample Control Record (Appendix 1B). The samples were then stored at 10°C in the Ecology Laboratory cool room (Figure 1). The data from the hard copies was uploaded to the electronic databases.

Figure 1 Soil storage at Landcare Research Tamaki 10°C cool room.

4.2 Soil bioassay protocol

Just prior to analysis, the soils were removed from the cool room and this movement recorded on the Sample Control Record (Appendix 1B). The samples were individually hand-mixed in their bag to ensure that the clods were broken and organic matter and roots combined. Subsamples were weighed into labelled zip-lock bags, the weight recorded on the Sample Control Record (Appendix 1B), and the remaining soil weighed. The sample date was written

on the waterproof label and put back in the bag, and the remainder of the soil samples returned to the cool room (date, time and mass recorded on Sample Control Record, Appendix 1B).

The soil samples for Scion and Plant and Food Research (PFR) were packed into cardboard boxes, secured with bubble-wrap and sent by registered overnight courier. An email was sent advising Scion and PFR that the samples had been dispatched. Scion and PFR confirmed receipt of samples via follow-up email or telephone communication. An example Shipping Receipt Form is given in Appendix 1C.

At the commencement of the soil bioassay analysis, the *sample* information was captured on the Analytical Data Sheet (Appendix 1D). The samples were bioassayed via the extended baiting protocol (Appendix 2). The extended baiting protocol was designed specifically for PTA detection – it utilises a soil-drying step and a moist-incubation step: specifically-tailored to recover oospore-forming species of *Phytophthora* (see Jeffers & Aldwinkle 1987). Further, the utilisation of a *Phytophthora*-specific agar (i.e. P₅ARPH) also helps target *Phytophthora* spp. by excluding *Pythium* spp. and higher fungi (such as basidiomycetes and ascomycetes; Jeffers 2006). Pure mycelia isolates were transferred and stored on PDA.

4.3 DNA isolation, amplification and sequencing

Mycelia was scraped off the PDA plates using a pipette tip and put into sterile Eppendorf tubes containing 420 µl of tissue extract buffer and 4.2 µl protease K enzyme from the Corbette robot DNA purification kit (Qiagen). After a 30-s vortex, the tubes were incubated at 56°C for 1 h, and centrifuged at 16000 rpm for 3 min. Then 220 µl of the supernatant was removed and loaded onto Corbette's DNA purification robot for DNA extraction. The robot was run according to the manufacturer's instructions.

The region spanning the internal transcribed spacer (ITS) 1-5.8S-ITS2 of the ribosomal DNA was amplified using ITS6 (Cooke & Duncan 1997) and ITS4 (White et al. 1990) primers. Successful amplifications were then confirmed by running the PCR products on a 1.5% agarose gel stained with ethidium bromide at 150V for 30 min. A sequencing PCR reaction was then undertaken and the completed reaction cleaned using Applied Biosystem's Big Dye Xterminator purification kit and loaded onto an ABI Genetic Analyser 3031XL sequencing machine (Applied Biosystems).

Pure isolates suspected to be PTA fungi had their ITS region sequenced and a NCBI/BLAST® search undertaken to compare with a known, validated PTA sequence deposited in GenBank®. These data were added to the Sample Control Record (Appendix 1B) and Analytical Data Sheet (Appendix 1D).

4.4 Retesting of selected soil samples

Upon completion of the first-round of testing, 18 soil samples were retested upon request of the KDJAR. The reasons this were various and as follows:

- No oomycete fungi recovered the first time

- Consistent ‘negatives’ (suspect ‘false negatives’)
- Only one lab bioassayed the sample soil
- Samples came from beneath / next to trees with PTA-lesions, but no PTA recovered from the soil sample
- Discretionary samples taken near, or adjacent to, sites with tree symptoms / known contaminated sites

4.5 iButton temperature studies

Following on from recommendations of the Planning and Intelligence Team, a temperature study was instigated to track the temperature profile of soil samples as they travelled from the field sample sites to Landcare Research and between labs. The intent was to monitor temperature throughout transit in case high temperatures occurred that might affect detection of PTA. The Thermochron iButton® was selected for this operation. Thermochron iButtons are self-contained, waterproof, portable temperature data loggers that record and store time and temperature data, for later analysis (see Appendix 1E).

5 Results

5.1 QA/QC findings

The internal audit held on 17 May 2011 found that all soil samples were in place and accounted for as recorded in the Sample Control Record (Appendix 1B). The internal audit held on 20 June 2011 found there to be no inconsistencies on the Sample Control Record (Appendix 1B). Out of 15 random soil samples stored at Landcare Research (LCR), there was found to be between 0.1 and 2% difference in sample weights. The slight differential is attributed to additional plastic bagging and condensation within the bags.

The individual QA/QC sample reports of Scion and PFR are provided in Appendices 3A and 3B. The samples received and analysed correspond to the Sample Control Record (Appendix 1B). All samples excess to the bioassay, provided to both laboratories, have been disposed of appropriately.

The temperature tag download for the 10°C cool room showed that there was between 5 and 10% variation in temperature around 10°C.

5.2 Soil sample mass variation

The first 15 soil samples received had a mass of c. 1.5 kg. As the programme progressed, soil samples increased in mass (see Figure 2). While the majority of samples ranged between 1 and 4 kg, there were some samples received that exceeded 5 kg.

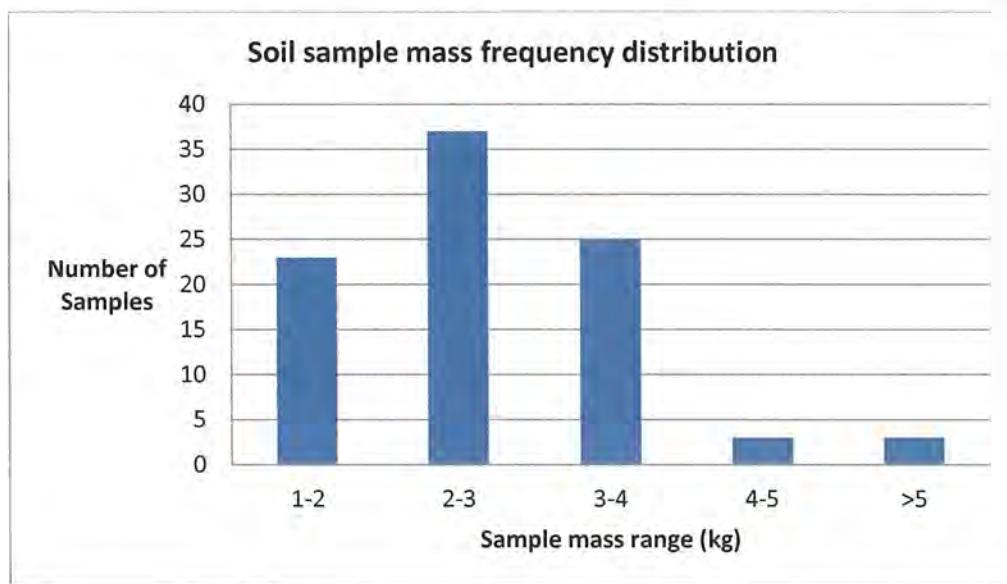

Figure 2 Soil sample mass variation received from Wildlands Consultants.

5.3 PTA presence

Phase 1 consisted of 91 soil samples from 24 sites (Appendix 4A) from which 15 PTA-positive samples were recovered. These 15 samples came from 7 of the 24 sites. These PTA-positive sites occur in the following five forest areas (see also Appendices 4A and 4B):

1. Waipoua Site 5 (Tree 1)
2. Omahuta Site 6 (Tree 1,2,3, Discretionary Sample 2)
3. Glenbervie Site 19A (Tree 2)
4. Glenbervie Site 19C (Tree 1-3)
5. Glenbervie Site 19D (Tree 1)
6. Punaruku (Russell Forest) Site 28 (Tree 1)
7. Great Barrier Island Site 21 (Tree 1-3).

5.4 Other *Phytophthora* species

Phytophthora cinnamomi was recovered from 60% of soil samples (e.g. Puketi, Paranui). On four occasions *P. cinnamomi* was recovered with PTA (e.g. Omahuta 6 Tree 3). *P. multivora* was recovered on five occasions (e.g. Puketi 2 Site 12, Tree 1). At Waipoua Site 5 and Great Barrier Site 21, *P. multivora* was recovered together with PTA. *P. multivora*, PTA, and *P. cinnamomi* were all recovered from the soil sample taken from Glenbervie Site 19C, Tree 1. While this information is outside of the contracted outputs, this information was requested by the Planning and Intelligence Team of the KDJAR.

5.5 Inter-laboratory PTA comparative recoveries

A total of 33 soil samples were run by all three laboratories (i.e. three replicates). Of these, 23 samples returned negative results by all three laboratories. Ten PTA-positive samples were identified but only once did all laboratories recover PTA simultaneously. On two occasions, two out of three laboratories recovered PTA, and seven times only one laboratory out of three recovered PTA (Table 1).

Scion and PFR received several soil samples from which they did not recover any oomycetes (Scion samples: 28–53, 67–77; PFR: 51, 52; 60–91). These samples came from the following sites and were part of two particular consignments:

Northland:

Russell 3
Omahuta 7, 8, 9, 10
AH Reed
Glenbervie 19B
Punaruku 28, 29

Coromandel:

Manaia 24
Lynch Stream 25
Kauaeranga Valley 2

Table 1 Breakdown of PTA recoveries between laboratories

	All negative	One lab positive PTA	Two labs positive PTA	Three labs positive PTA
Triplicate (<i>n</i> = 33)	23	7	2	1
Duplicate: LCR v. Scion (<i>n</i> = 10)	10	0	0	-
Duplicate: LCR v. PFR (<i>n</i> = 28)	26	1	1	-
Duplicate: Scion v. PFR (<i>n</i> = 6)	5	1	0	-
LCR (<i>n</i> = 1)	1	0	-	-
Scion (<i>n</i> = 10)	10	0	-	-
PFR (<i>n</i> = 3)	1	2	-	-

LCR = Landcare Research; PFR = Plant and Food Research

5.6 Repeat soil bioassays

Eighteen soil samples were duplicated and each lab carried out 12 bioassays (Table 2).

Table 2 Results of repeat bioassays

Laboratory code	Sample number	Lab	June result	LCR repeat	Scion repeat	PFR repeat
1	29	LCR, PFR	Nil	Pc	Not tested	Nil
2	33	LCR, Scion	Nil	Pc	Pc, Pyth	Not tested
3	34	LCR, PFR	Nil	Pc	Not tested	Pyth
4	35	LCR, Scion	Nil	Pc	Pc	Not tested
5	37	LCR, PFR	Nil	Septate fungus	Not tested	Nil
6	38	LCR, Scion	Nil	Pc	Pc	Not tested
7	45	PFR, LCR	Nil	Zygomycetous fungus	Not tested	Pyth
8	47	PFR, Scion	Nil	Not tested	Pyth	Pyth & Pm
9	48	PFR, LCR	Nil	Pc	Not tested	Pyth
10	49	PFR, Scion	Nil	Not tested	Pc, Pyth	Pyth & Pm
11	50	PFR, LCR	Nil	Pc	Not tested	Pyth
12	61	PFR, Scion	Nil	Not tested	Nil	Nil
13	62	Scion , LCR	Nil	Pc	Pc, Pyth	Not tested
14	63	Scion , PFR	Nil	Not tested	Pyth	Pyth
15	64	Scion , LCR	Nil	Pc	Nil	Not tested
16	89	Scion , PFR	Pc	Not tested	Pyth	Pyth
17	90	Scion , LCR	Pc	Pc	Pc, Pyth	Not tested
18	91	Scion , PFR	Pc	Not tested	Nil	Pyth

NB: Pc = *P. cinnamomi*, Pm = *P. multivora*, Pyth = *Pythium* sp.

We did not recover PTA from any of the samples that were repeated. This is in support of the June analysis results. The recovery of other by-catch oomycete fungi from at least one of the laboratories supports the validity of the negative PTA result, and suggests that the sample(s) had not been compromised by temperature or other harmful factors.

5.7 iButton temperature data

Appendix 1F-1–4, provides the temperature profiles within consignments of soil – two consignments sent to LCR and one each to Scion (1F-1), LCR to PFR (1F-2), Corromandel to LCR (1F-3), and Waipoua to LCR (1F-4). The first two profiles represent uninsulated (i.e. cardboard box with no chill-bricks) soil transport from LCR to the diagnostic labs of Scion and PFR. Both plots show a similar trend of the temperature falling to around 10°C overnight (in transit on 3 August 2011), and then a rise in temperature as the samples were unpacked on the 4 August 2011, around lunchtime (Appendix 1F-1, 1F-2). Temperatures during transit ranged from 8° to 18°C.

Appendix 1F-3 plots the temperature profile from the Corromandel region back to LCR – this represents an insulated transit (with chill-bricks). The temperature range for this trip was between 2° and 25°C, with a period of constant temperature around 8°C. This sort of temperature variation is worth noting on the soil samples associated with this consignment.

The final temperature profile is from the Waipoua region (Dargaville) to LCR via in an insulated (polystyrene container) with insulated chill-bricks (Appendix 1F-4). This profile demonstrates the combined efficacy of using insulated containers (i.e. polystyrene) in combination with insulated chill-bricks (i.e. chill-bricks wrapped in newspaper or bubble-wrap to prevent direct cold shock on the soil sample). The temperature profile has a gradual decline in temperature from 14°C to the optimum temperature of 10°C.

6 Discussion

6.1 Soil sample variability

The recommended soil sampling procedure, designed as part of the SOP, proposed obtaining composite soil samples in the range of 1–1.5 kg from each tree (Dick & Bellgard 2010). The evidence of variability in soil sample mass, which is occurring at the point of sampling, means that certain sites (and particular trees) are being over-represented. This also has implications with respect to the relative representativeness of the sub-sampled aliquots used for the soil bioassay.

6.2 PTA presence

Among the forest areas with PTA, there was a marked clustering of PTA recoveries from four of the sites. These clusters occurred in the following forest areas:

1. Waipoua Site 5 2 PTA recoveries
2. Omahuta Site 6 4 PTA recoveries
3. Glenbervie Site 19 5 PTA recoveries
4. Great Barrier Island Site 21 3 PTA recoveries.

6.3 Other *Phytophthora* species

The extended baiting protocol we are using was designed specifically for PTA extraction and recovery. Any other *Phytophthora* spp. we get is ‘by-catch’, and frankly, should be considered as a contaminant in the process. The differences in extraction rates of other *Phytophthora* spp. (such as *P. cinnamomi*), from the recent round of retested soil samples, almost certainly reflects slightly different drying conditions, and nothing else. In the PFR laboratory in Hawke’s Bay, the soil is very thoroughly air-dried in the very dry Hawke’s Bay environment. The other labs are probably in moister environments, so the drying may not be as thorough, and *P. cinnamomi* suppression not as great. As such, interpretation of the ‘by-catch’ data from a technique that is designed to *minimise* that by-catch should be done with extreme caution (as is beyond the scope of this brief). We provide the following discussion on ‘other’ *Phytophthora* spp. to highlight the risks posed by these ‘other’ introduced plant pathogens to the native plants of New Zealand’s kauri forests.

6.3.1 *Phytophthora cinnamomi*

Phytophthora cinnamomi is considered to have been introduced into New Zealand sometime during the last 1000 years. *P. cinnamomi* is now widely distributed in New Zealand indigenous forests, being isolated from soils in apparently undisturbed forests in isolated situations (Johnston et al. 2003). *P. cinnamomi* is widely distributed in kauri forests, having been isolated from soil beneath mature, apparently undisturbed stands of kauri in remote localities, as well as from beneath young, regenerating stands (Podger & Newhook 1971). It has been speculated that *P. cinnamomi* may be influencing kauri forest establishment and succession through pre- and post-emergence damping-off, as well as causing disease in stands of older trees (Podger & Newhook 1971; Horner 1984). *P. cinnamomi* may also be influencing other susceptible plant species, known to be associated with kauri in infested sites. Robertson (1970) identified the following species as ‘severely infected’ by *P. cinnamomi* after a 9-month inoculation trial; puka *Meryta sinclairii*, taraire *Beilschmiedia tarairi*, tawa *B. tawa*, ramarama *Lophomyrtus bullata*, pohutukawa *Metrosideros excelsa*, kōwhai *Sophora tetraptera*, titoki *Alectryon excelsus* and puriri *Vitex lucens*.

6.3.2 *Phytophthora multivora*

Phytophthora multivora is a new species recognised from Western Australia, where it is associated with *Eucalyptus* decline as well as disease of a range of other native plant species (Scott et al. 2009). It is morphologically similar to *P. citricola*, which has been known to occur in New Zealand since the 1930s (Dingley 1969; Beever et al. 2006). A number of New Zealand *P. citricola* isolates collected over many years and curated in culture collections have been re-examined in light of the new descriptions and gene sequence data and found to be *P. multivora*. The host-range and risk that *P. multivora* poses to kauri and native plant species are at present unknown. Recently, Ho et al. (2010) recovered *P. multivora* from kawakawa *Macropiper excelsum* trees displaying symptoms of leaf yellowing, branch wilt, and sudden collapse in the Auckland Region and Whangarei. Kawakawa trees in Oratia and Auckland initially showing signs of decline have subsequently all died (Ho et al. 2010). Newhook (1989) noted that *Phytophthora* species invade chiefly unsterilised tips of feeder rootlets, and that rootlet death may be followed by rootlet replacement. Further studies are necessary to ascertain the infection/disease implications for other currently unknown, but potentially susceptible plant taxa occurring with kauri in these sites infested with *P. multivora*.

6.4 Establishment of 'cool-chain' for soil transport

In order to obtain consistent conditions for the transport of soils samples, it is clear that an insulated container and the use of insulated chill-bricks results in gradual cooling and then maintenance of optimum temperature conditions around 10°C ($\pm 50\%$).

The repeated bioassays of 18 soil samples resulted in recovery of no PTA; this was consistent with the earlier June results. The presence of a variety of 'by-catch' oomycetes supports the validity of the sample and suggests that high temperatures had not occurred in transit (Table 2).

7 Conclusions

- Using the extended soil baiting method, PTA was recovered from the following soil samples submitted by Wildlands Consultants:
 - Waipoua Site 5
 - Omahuta Site 6
 - Glenbervie Sites 19A, 19C and 19D
 - Punaruku (Russell Forest) Site 28
 - Great Barrier Island Site 21.
- There was marked clustering of PTA-positive recoveries from within an infested site.
- *P. cinnamomi* was recovered from 60% of the soil samples.
- *P. multivora* was recovered from 5.5% of the soil samples – with *P. multivora*, *P. cinnamomi* and PTA being recovered together from one soil sample.
- There was considerable variation between the sizes of soil samples and standardisation would be desirable.
- Preventing the overheating of soil samples is vital as PTA mycelium is killed at 29°C and viability of oospores will likely be reduced at temperatures above 45°C.
- Retesting of 18 samples did not alter the results as reported in June 2011 (across all three labs).

8 Recommendations

- Standardise soil volume at point of sampling (1–1.5 kg).
- Modify the QA/QC procedure to include temperature monitoring of soil from the point of sampling through to the analytical laboratory. Temperature data can be analysed upon receipt of each sample, to establish if significant temperature variations (i.e. $>30^\circ\text{C}$) have occurred in transit.
- Establish a 'cool chain' of custody to maintain soil sample temperatures below 25°C and preferably within the range 10° $\pm 50\%$.
- Temperature tags (e.g. iButtons®) should accompany soil from the point of sampling, through to laboratories.

- Delimit extent of contaminated sites through further sampling (including, where appropriate, tissue sampling).

Appendix 1C – Sample Shipping Receipt Form

Suggested additional QA/QC form to accompany soil consignment from point of sampling through to inter-laboratory movements

1. Sender	2. Carrier	3. Receiver
Signature _____ Date _____ Sent from _____ _____	Company _____ Signature _____ Date _____ B/L no. _____ Pkg tracking no. _____	Courier from depot Signature _____ Date _____ Lab Custodian Signature _____ Date _____ Condition upon receipt _____

4. Shipment description	Temp tag no. (if any)	Seal intact?
Number of packages _____ Sealed (yes or no) _____ Types of containers _____ Condition prior to shipment _____ _____	_____ _____ _____ _____	_____ _____ _____ _____

5. Contents			
Sample ID number	Type of sample	Temp tag (yes or no)	Condition (damaged, loss of liquid, etc.)

Appendix 1D – Analytical Data Sheet

Spreadsheet tracking the analytical stages for the LCR soil samples

Date	Sample no.	Air-dried	Moist incubated	Flooded / baited	Plated to phyt. selective media	PTA	DNA seq. confirmed
20/03/11	001	20/03/11	22/03/11	25/03/11	28/03/11	No	Yes

Appendix 1F – Temperature profiles for soil samples

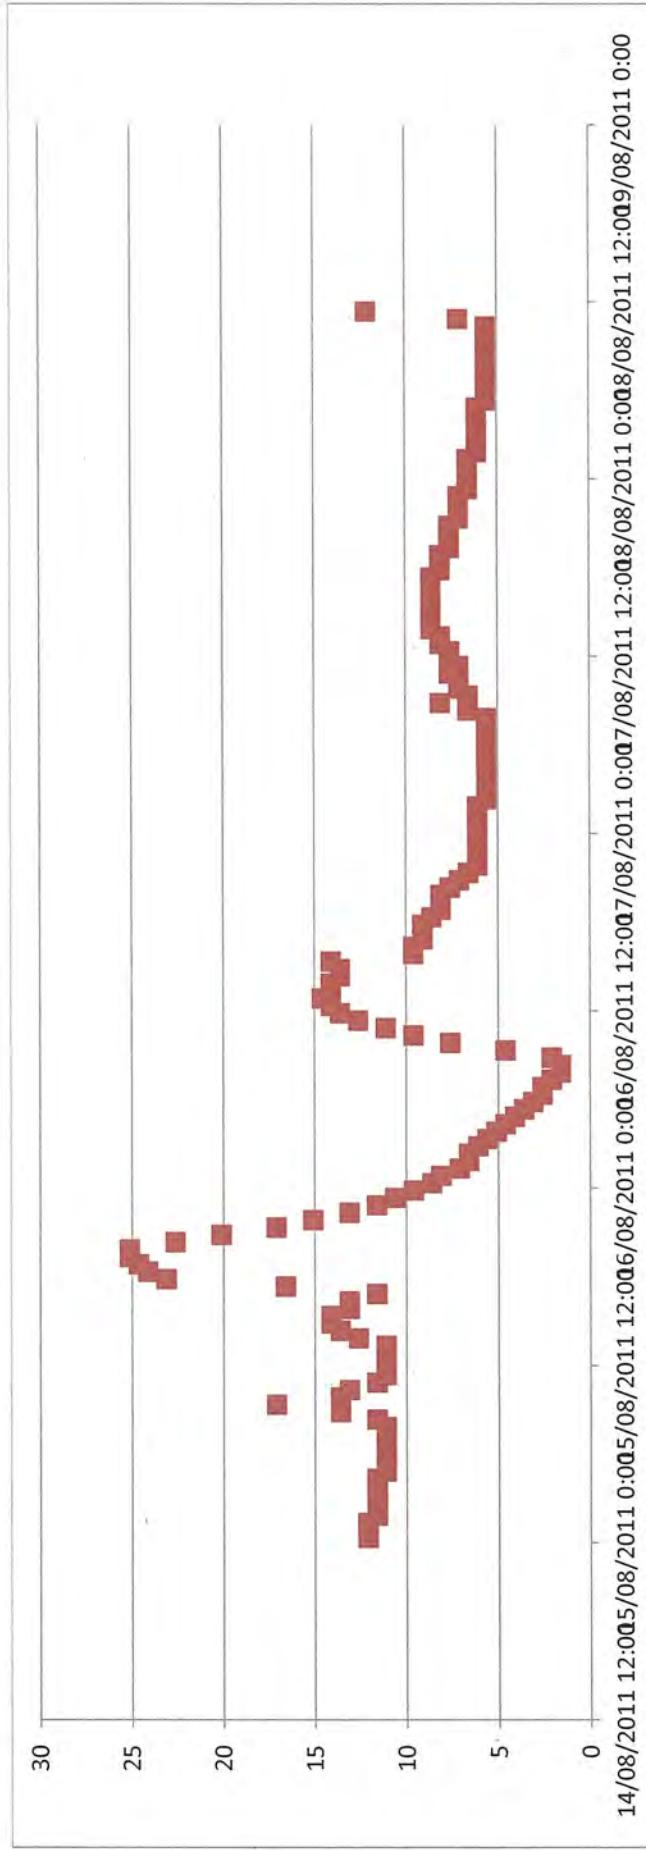

Appendix 1F-1: LCR to Scion

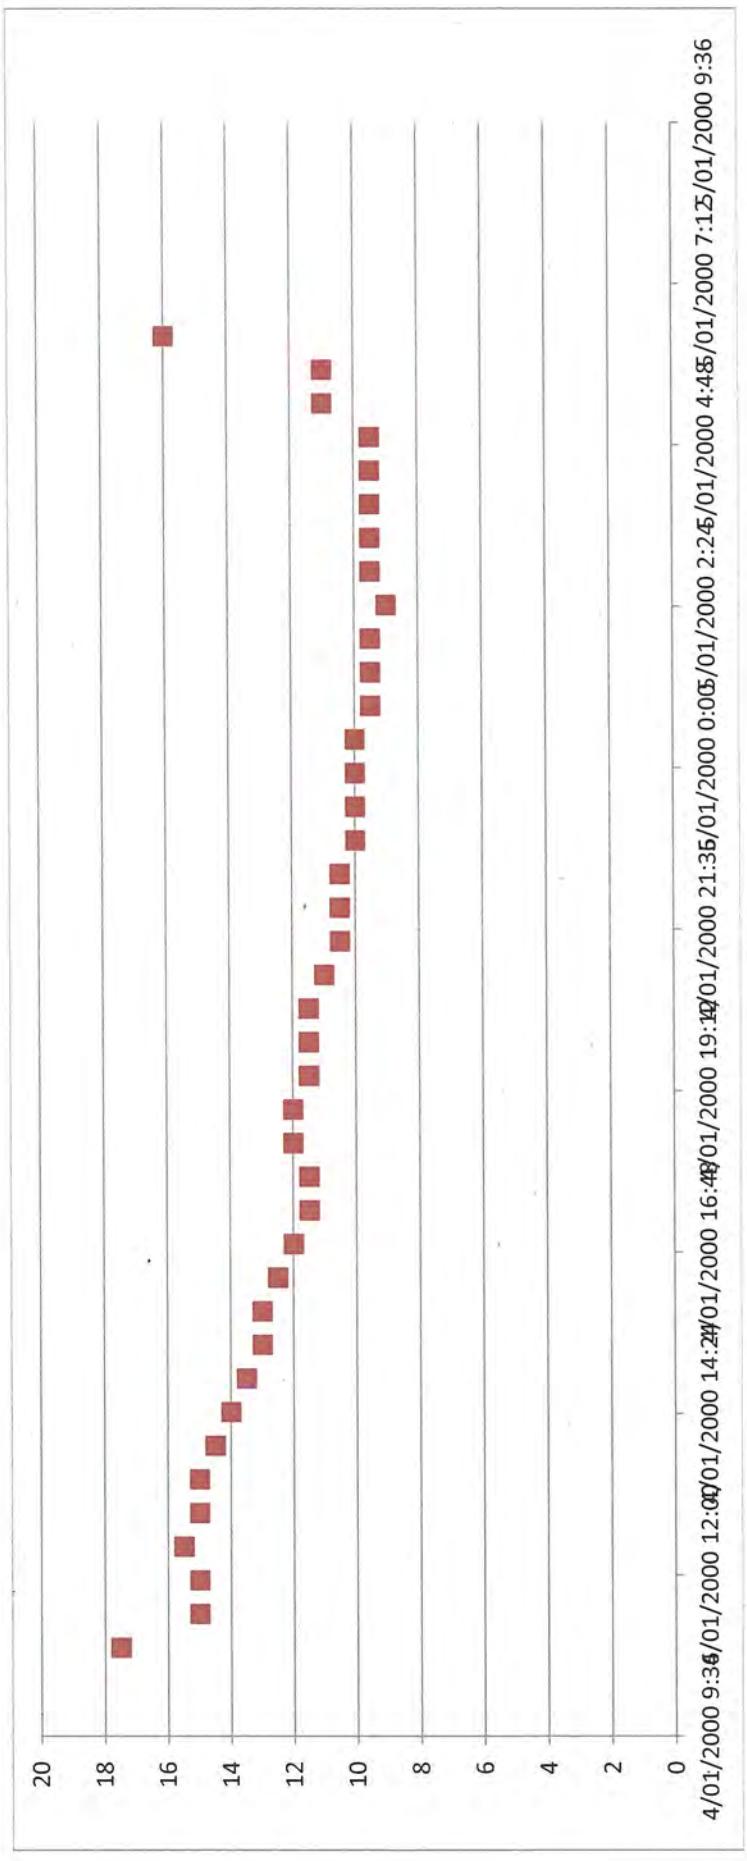

Appendix 1F-2: LCR to PFR

Appendix 1F-3: Corromandel to LCR

Appendix 1F-4: Waipoua to LCR

Appendix 2 – Soil SOP

Drying of soil samples (pretreatment-phase)

- Thoroughly mix soil samples in their bag to remove lumps
- Label container, measure out at least 100 g
- Air-dry on lab bench for 2 days
- Check soil each day and crumble clods with pop-sticks

Moist incubation (stimulating-phase):

- Using a spray-squirt bottle, moisten soil samples in containers with RO water (using a fine mist)
- Spray enough moisture to make soil surface shine. Respray after 1 h, targeting dry spots / clods of soil
- Apply lid loosely
- Incubate in light for 4 days at room temperature (20–22°C)

Bait tissue preparation

- One day after the commencement of moist incubation, prepare desired amount of lupin seed, allowing for five lupins per soil bioassay.
- Needles of Himalayan cedar (*Cedrus deodara*), harvested directly off tree
 - Pull off whorls
 - Pull needles off from leaf base
 - Five needles per soil bioassay

Bioassay

- Inundate the soil very slowly with RO or distilled water to cover soil (approx. 500 ml for 1-L take-away container)
- Minimise soil disturbance and water turbulence
- The soil must not be mixed once flooded
- Sprinkle five 2-cm lengths of Himalayan cedar leaflets on water surface
- Add five lupin radicles to the water surface
- Incubate at 20°C in light for 2 days.

Bait processing

- After 2 days remove the bait tissues
- Wash in single rinse of sterile RO water
- Soak in 70% ethanol (ETOH) for 30 seconds
- Remove from ETOH, rinse in sterile RO water
- Blot dry on paper towels
- Place needles/lupins onto *Phytophthora* selective agar (P₅ARPH)
- Label and seal plates and incubate in the dark at 18–20°C for 2–4 days

Colony isolation

- Check agar plates after 4 days for characteristic cultures
- Sub-culture to PDA
- If cultures are free of contamination, sub-culture to PDA

N.B. If using V8-enriched PARPH, then oospores produced in 4 days.

Appendix 4A – Results spreadsheet

PTA recoveries highlighted in yellow were confirmed by ITS sequence confirmation. PTA recoveries highlighted in red were identified by morphology. The 'Valid Sample' column is a designation based upon the interpretation of soil recoveries from all samples from within a site (n/t = not tested by that lab).
